1 Introduction

George Bush's 2003 State of the Union address contains the following line.

(1) Yet there's power—wonder-working power—in the goodness and idealism and faith of the American people.

To most people this sounds like, at worst, a civil-religious banality, but to a certain segment of the population the phrase *wonder-working power* is intimately connected to their conception and worship of Jesus. When someone says (1), they hear (2).

(2) Yet there's power—Christian power—in the goodness and idealism and faith of the American people.

❖ ❖ ❖

In a 2016 Reddit AMA Green Party presidential candidate Jill Stein was asked about the party's platform vaccines and homeopathy. She said:

(3) By the same token, being "tested" and "reviewed" by agencies tied to big pharma and the chemical industry is also problematic.

Even though Stein said she thought vaccines work, across the internet she was accused of being an anti-vaxxer and pro-woo due to phrases like *big pharma*, which to people familiar with alternative-medicine discourses know is demonized as selling poison for profit. They heard:

(4) By the same token, being "tested" and "reviewed" by agencies tied to big pharma and the chemical industry, who sell unsafe vaccines to make a buck, is also problematic.

❖ ❖ ❖

On a 2014 radio program, Representative Paul Ryan said the following.

(5) We have got this tailspin of culture, in our inner cities in particular, of men not working and just generations of men not even thinking about working or learning the value and the culture of work.

He was criticized shortly after by fellow Representative Barbara Lee for making a "thinly veiled racial attack". This is because the phrase *inner-city* is code or euphemism for African American neighborhoods (espcially stereotypically racialized views of such neighborhoods). Many people heard Paul Ryan say:

(6) We have got this tailspin of culture, in our African American neighborhoods in particular, of men not working and just generations of men not even thinking about working or learning the value and the culture of work.

❖ ❖ ❖

All three of these examples illustrate the notion of a *dogwhistle*—that is, language that language that sends one message to an outgroup while at the same time sending a second (often taboo, controversial, or inflammatory) message to an ingroup.

- Dogwhistle language has been explored quite a bit in political science and political economy (e.g., Calfano and Djupe 2008; Goodin and Saward 2005; Hurwitz and Peffley 2005; Mendelberg 2001), and even in their experimental literatures.

  - e.g., Albertson 2015 shows experimentally that examples like (1) do in fact improve a speaker's appeal to religious voters, while slipping right by unreligious voters, unlike uncoded religious appeals like (2), which are punished by non-religious voters.

- The linguistic literature on dogwhistles is practically non-existent.

- Only Stanley 2015 provides a substantive semantic / pragmatic proposal, where dogwhistles are Pottsian CIs, contributing an at-issue component for the outgroup audience and a non-at-issue component that potentially only the ingroup is sensitive to.

- In this talk we argue against a CI account of dogwhistles and instead propose alternative, purely pragmatic account combining aspects of McCready 2012, Burnett 2016; Burnett 2017, and which we think better accounts for the core their core properties.

In broad strokes, we make the novel proposal that dogwhistles come in two types.

- The first concerns covert signals that the speaker has a certain persona, which we model by extending the *Sociolinguistic Signalling Games* of Burnett 2016; Burnett 2017.

- The second involves sending a message with an enriched meaning whose recovery is contingent on recognizing the speaker's covertly signalled persona.

2 Against a CI account

Stanley 2015 argues that dogwhistle language involves a conventional non-at-issue component along the lines of more familiar expressions like slurs, honorifics, etc.

- A slur like *kraut* would have AI-component "German" and a NAI-component "I hate Germans".

- A dogwhistle like *welfare* would have AI-component "the SNAP program" and a NAI-component "Blacks are lazy".

- In general, terms which carry both AI and NAI components can be referred to as *mixed content bearers*.

There are a series of reasons to believe that dogwhistles are not mixed content bearers.

Knowledge argument.
The requirements for knowing the meaning of dogwhistles seem quite different from those for widely accepted cases of mixed content.

- Take the case of pejoratives. Can a speaker know what *kraut* means without knowing it is derogatory? No.

- Conversely, can a speaker know what *welfare* means without knowing this association with Cadillacs, etc. (p. 158-9)?

- We think the answer is: Yes. The whole idea of a dogwhistle is that the (so-called) NAI component is not accessible to some speakers.

- So the NAI part is not part of conventional meaning.

Objection!
Maybe we're just dealing with different dialects?

- This argument seems to beg the substantive question, but there are other reasons to think it incorrect.

- This view might explain the effect of dogwhistles in mixed company, but does not explain the use of dogwhistles with an in-group.

  - Under a dialect account, dog-whistle language should also be what is used when talking to an in-group because this is just what the words mean for the audience.

  - This doesn't seem right. Dogwhistles, by definition, are not needed when talking to an in-group and can be disposed of, which wouldn't make sense if the subtext of dogwhistle were part of its conventional meaning for the in-group.

  - Ultimately what we'll propose is that we have distinct groups of speakers, but the way they are distinct is not a way characteristic of how 'genuine' dialects work, but rather involves different background knowledge about language *use*.

'What is said' by a dogwhistle?

- The use of dogwhistles is prompted by a desire to 'veil' a bit of content, but still to convey it in some manner. Deniability is essential.

- If a bit of content is conventional, it's not deniable any longer. This can be seen with pejoratives, which clearly carry conventional NAI content.

(7)   A: Angela Merkel is a kraut.
       B: What do you have against Germans?
       A: #I don't have anything against Germans. Why do you think I might?

Such dialogues are fine with dogwhistles; in the following, there seems to be no entailment that A has the relevant attitude.

(8)   A: Eric is on welfare.
       B: What do you have against social programs?
       A: I don't have anything against social programs. Why do you think I might?

> Generalizing, we can identify a dialogue-based test for conventional content: in a dialogue in which participant A says 'X', where $[\![X]\!]$ is a mixed content bearer with AI content Y and NAI content Z and participant B responds with 'It's not cool to say Z', it is incoherent for A to respond 'I didn't say that Z" if Z is conventional content.

- By this test, dogwhistles can be concluded not to be conventional.

In the following sections we develop an account of dogwhistle language that avoids problems with conventionalized CI analysis, while accounting for what we take to be its core properties.

- Dogwhistles are not part of conventional content, so speakers are able to avoid (complete) responsibility for what they convey.

- Dogwhistles are semi-cooperative—that is, they are meant to be under-informative to one segment of the audience, while communicating a particular message to another.

- While deniable, dogwhistles are risky. Being detected using a dogwhistle by the wrong party should be costly.

3   Flavors of dogwhistle

While dogwhistle language is often treated as a uniform phenomenon, we think there are two prototypical cases (though they smear into one another):

Type 1: The content sends one message to all audience members, while the whistle transmits the speaker's true identity to a sub-audience.

- The Stein and Bush cases above probably best fit in this category.

    - Stein's "Big Pharma" just means large, faceless pharmaceutical corporations (parallel to "Big Agriculture", etc.), but she flagged herself a vaccine denier because that phrase is primarily used in vaccine-denial (and alternative medicine) discourse.
    - Bush's "wonder-working power" probably doesn't convey some secondary message about the power at hand, but instead just flags him as an evangelical because only they talk like that.

Type 2: The content sends one message to all audience members, while the whistle sends places an addendum on that message for a sub-audience.

- The Ryan case above best fits this category. His use of "inner city" conveys to all audiences a geographical location inside cities, but then to a sub-audience, it specifically picks out African American neighborhoods in those cities.

- Of course, Ryan's utterance will also allow a listener to infer things about Ryan's identity as in Type 1 examples—this is especially true if the whistle is detected.

We take each of these cases in turn, starting from the simpler Type 1 and then expanding into Type 2.

4   Type 1 dogwhistles & sociolinguistic signalling games

In recent work, Burnett 2016; Burnett 2017 pioneers the use of Bayesian signaling games to model identity construction through sociolinguistic variation.

- We take Type 1 dogwhistles to be only slightly more complex verions of sociolinguistic identity construction through variation of the kind Burnett (2016) and Burnett (2017) discuss.

- Type 2 dogwhistles will be an extension of these games where amended messages are sent to a sub-audience that work in concert with the kind of identity construction we see in Type 1 dogwhistles.

Burnett's Social Meaning Games which have the following simplified architecture (which we modify / elaborate further below):

- Players

    - a speaker S
    - a listener L

- Actions for players

    - The speaker chooses a persona p from the space of personae P
    - Based on their persona, the speaker chooses a message $m \in M$ to send to the listener.
    - Based on the message, the listener chooses a response $r \in R$, which in the simplest case we can identify with selecting an element of P—i.e., identifying the speaker's persona.

- Utilities functions for players

– U_S/U_R—functions from $P \times M \times R$ to $\mathbb{R}$, which represents payoffs for every possible combination of actions.

In the kinds of games we consider, the optimal action choices for speakers and listers along

- The speaker's utility is maximized by picking a message that sends the most information to the listener about the persona they want them to assign to them.

- The listener's utility is maximized if they extract the most information they can about a speaker's persona given their message.

We now elaborate on these ingredients and model the behavior of Type 1 dogwhistles.

- The set of personae P is a set of maximally consistent sets of properties.

  – For instance, in the Stein case, the relevant properties might be: ANTI-VAX, PRO-VAX, ANTI-CORPORATE, PRO-CORPORATE

  – Maximally consistent subsets of these properties would be:
  {ANTI-VAX, ANTI-CORPORATE},
  {ANTI-VAX, PRO-CORPORATE},
  {PRO-VAX, ANTI-CORPORATE},
  {PRO-VAX, PRO-CORPORATE},
  given that one's corporate stance is, in principle, separable from one's stance on science, though it is incoherent to be both anti-vax and pro-vax or pro- and anti-corporate.

- Messages $m \in M$ may have their normal denotational meaning $[\![m]\!]$, but for the sake of Type 1 dogwhistles, messages also have a social meaning, which they take from P, written $[m] \in P$.

  – While a message m is associated with a particular persona, we often work with a related object $c(m) = \{n \in M | m \cap n \neq \emptyset\}$

  – We can think of $c(m)$ as denoting all of the personae that are consistent with m

  – Thus, assuming $[Big\ Pharma] = \{$ANTI-VAX, ANTI-CORPORATE$\}$, we also have $c(Big\ Pharma) =$
  {ANTI-VAX, ANTI-CORPORATE},
  {ANTI-VAX, PRO-CORPORATE}, and
  {PRO-VAX, ANTI-CORPORATE}

  – That is, using *Big Pharma* is consistent with any persona that is not {PRO-VAX, PRO-CORPORATE}

With this in mind, games now have the following elaborated action structure.

- The speaker picks a persona and a message—e.g.,
$\langle\{$ANTI-VAX, ANTI-CORPORATE$\}, Big\ Pharma\rangle$

- The listener then identifies the speaker's persona based on their message from P:
{ANTI-VAX, ANTI-CORPORATE},
{ANTI-VAX, PRO-CORPORATE},
{PRO-VAX, ANTI-CORPORATE},
{PRO-VAX, PRO-CORPORATE}—while knowing that the social meaning of *Big Pharma* rules out the persona {PRO-VAX, PRO-CORPORATE}

Calculating utilities for the speaker and listener over choices of these actions will be based on conditionalization:

(9) $Pr(p|m) = \frac{Pr(p\&m)}{Pr(m)}$ "The probability of persona p given message m"

For Burnett 2016; Burnett 2017, it's computed as follows:

(10) $Pr(p|m) = \frac{Pr(\{p\} \cap c(m))}{Pr(c(m))}$

- $Pr(p)$ is given by the listener's prior beliefs about the speaker's persona which is a probability distribution over P.

- Because messages are identified with their social meaing (e.g, $[Big\ Pharma] = \{$ANTI-VAX, ANTI-CORPORATE$\}$), the probability of $p\&m$ when they are consistent with it is just the probability of the persona—i.e., $Pr(p)$

- $Pr(m)$ is the probability of all the personae consistent with m, namely $Pr(c(m))$

Here is where we have to begin to diverge from Burnett 2016; Burnett 2017. The reason is that we want the dogwhistle effect to arise from listeners being unaware (or uncertain) about the close connection between some bit of language an a persona.

- We want listeners to have beliefs about a speaker's persona...

- ...but also beliefs about how personae and messages are connected.

That is, listeners have prior over P, but also beliefs about $P(m|p)$—namely how closely messages are linked to particular personae.[1]

- We can now update a listener's belief about the speaker's persona given their message using Bayes' theorem.

- Note that the probability of the message can be directly computed.

---

[1]The term "belief" might be a bit too strong. Listeners will have formulated, from their experience, some idea about the particular social messages different kinds of people send and at what frequency. This will obviously differ across listeners.

(11) $Pr(p|m) = \frac{Pr(p)Pr(m|p)}{Pr(m)}$

(12) $Pr(m) = \sum_{p \in P} Pr(m|p)Pr(p)$

While we need this complication for Type 1 dogwhistles, this is a trivial extension of Burnett 2016; Burnett 2017.

- Burnett's analysis is recovered by just assuming the likelihood (i.e., $Pr(m|p)$) is 1 whenever m and p are consistent.

- One way to think about this is that in Burnett's system, the probability of hearing a p-consistent message with p is just the probability of p because messages and personae are perfectly coupled.

- Instead, what we allow is for messages to more strongly or weakly signal types that they are consistent with.

The final ingredient we need to provide utility functions is some way to encode the fact that speakers don't just *report* their personae, but construct them in concert with their listeners.

- Speakers want to present themselves in a certain way.

- Speakers will also be sensitive to whether listeners will approve of that persona or not.

- In adversarial contexts, a speaker might have to juggle presenting a safe persona with a persona they might prefer to present (or prefer to present to another audience that might be listening)—this is when dogwhistle language become useful.

Along these lines, we follow Burnett 2017; Yoon et al. 2016 in assuming that the utility calculation takes into account the message's social value, which is given by two functions:

- The speaker has a function ν_S that assigns a positive real number to each persona representing their preferences.

- The listener has a function ν_L that assigns a real number (positive or negative) to each persona representing their (dis)approval.

We can now calculate the speaker's utility, though we diverge again from Burnett 2016; Burnett 2017.

- In that work utilities are computed over persona-message pairs, which allows for reasoning about what persona would be useful to convey.

- We instead focus on what message should be sent given the particular persona structure and how personae might be received.

- Thus, we consider a generalized formulation which calculates the utility for the message itself, without considering the particular persona it is intended to convey.

Here, the utility is dependent on the affective values of the range of personae consistent with the message, dependent on the likelihood that the particular persona is recovered given the message, as follows:

(13) $U_S^{Soc}(m, L) = \sum_{p \in [m]} ln(Pr(p|m)) + \nu_S(p)Pr(p|m) + \nu_L(p)Pr(p|m)$

When only one listener is addressed, dogwhistles reduce to ordinary social meaning; the speaker should choose a signal which maximizes U_S^{Soc}.

- Dogwhistles come into their own when speakers address groups of individuals with mixed preference over personae, different priors for the speaker's persona, and different experiences about the likelihood of a persona given a message.

- The simplest way to assign utilities to the group case is to sum over all listeners; we will assume this metric in the following.

(14) $U_S^{Soc}(m, G) = \sum_{L \in G} U_S^{Soc}(m, L)$

Note, though, that we think this should only be taken as a starting point.

- There are probably cases in which this way of calculating utilities overridden— e.g., if one particular powerful person in the audience is known to have a highly negative affective value for a particular persona which she is likely to recover.

- Also, in the case of a particularly pernicious persona (i.e. one for which ν_L yields an extremely low value), the possibility of later penalty may preclude the use of the dogwhistle in the first place despite present advantage. Modeling this requires a move to a repeated game setting (cf. McCready 2015) and we will leave its analysis for later work.

What should speakers do?
Note that the speaker's utility depends only on: (i) the informativity of sending the message given the various persona in play, the speaker's value for particular personae, and the speaker's beliefs about the how the listener(s) will (dis)approve of particular personae.

- This means we can reason about the speaker's behavior without discussing the listener's utility; we require only the aspect of hearer utility that plays into speaker preferences.

- We plan to discuss the listener's optimal behavior in future work.

5 A case study of Type 1 dogwhistles

Jill Stein is in a predicament.

> She has just been asked about vaccines. She knows her base is basically all anti-corporate, but she also knows her base contains a passionate anti-vaxx minority that hold a position others in her party don't like. She knows that this her anti-corporate bona fides are solid, but the question wouldn't be coming up unless there was some uncertainity about her stance on vaccines. She realizes, though, this is the perfect occasion for a dogwhistle. Her audience has only three types of listeners—the passionate anti-vaxxer, the clueless pro-vaxxer, and the knowledgeable pro-vaxxer—and she can satisfy most everyone while maintaining plausible deniability if her strategy is discovered.

We assume that Stein is chooses between messages whose social meanings always mark her has anti-corporate, but mark her as pro- or anti-vaccine.

Social meanings	Consistent Personae
big pharma	{ANTI-VAXX, ANTI-CORPORATE}
	{ANTI-VAXX, PRO-CORPORATE}
	{PRO-VAXX, ANTI-CORPORATE}
corporate scientists	{PRO-VAXX, ANTI-CORPORATE}
	{ANTI-VAXX, ANTI-CORPORATE}
	{PRO-VAXX, PRO-CORPORATE}

We further assume that Stein takes all listeners to have the following prior about her persona. That is, they believe that she is probably anti-corporate, but it is equally probably that she is pro- or anti-vaxx (which is why the question is being asked).

Personae	Priors
{PRO-VAXX, PRO-CORPORATE}	.05
{PRO-VAXX, ANTI-CORPORATE}	.40
{ANTI-VAXX, PRO-CORPORATE}	.15
{ANTI-VAXX, ANTI-CORPORATE}	.40

She further supposes her audience is polarized on this issue, but there is structure to this polarization. Often constituencies are composed of highly-motivated, warring subconstituencies with a larger center with opinions, but are somewhat less invested.

- Along these lines, we assume the anti-vaxxers clearly care a lot about the issue, and the savvy pro-vaxxers, as demonstrated by their knowledge of anti-vaxx discoursem care a lot about Stein's stance.

- If she is detected as liking vaccinations at all, the anti-vaxxers will be angry and savvy pro-vaxxers will love her, and vice versa.

$\nu_{\mathbf{L}}(\mathbf{p})$ for Anti-Vaxxers

Personae	Values
{PRO-VAXX, PRO-CORPORATE}	-100
{PRO-VAXX, ANTI-CORPORATE}	-100
{ANTI-VAXX, PRO-CORPORATE}	100
{ANTI-VAXX, ANTI-CORPORATE}	100

$\nu_{\mathbf{L}}(\mathbf{p})$ for Savvy Pro-Vaxxers

Personae	Values
{PRO-VAXX, PRO-CORPORATE}	100
{PRO-VAXX, ANTI-CORPORATE}	100
{ANTI-VAXX, PRO-CORPORATE}	-100
{ANTI-VAXX, ANTI-CORPORATE}	-100

An unsavy pro-vaxxer has more attenuated belief. We assume that if they discover Stein to be anti-vaxx, they will highly object. That said, the vaxx war is not something they are highly invested in. If Stein is detected to be pro-vaxx, they are happy, but it's consider a kind of default position and so not as big a deal as for the savvy pro-vaxxers.

$\nu_{\mathbf{L}}(\mathbf{p})$ for Unsavvy Pro-Vaxxers

Personae	Values
{PRO-VAXX, PRO-CORPORATE}	75
{PRO-VAXX, ANTI-CORPORATE}	75
{ANTI-VAXX, PRO-CORPORATE}	-100
{ANTI-VAXX, ANTI-CORPORATE}	-100

While the audience cares a lot about Stein's persona, we assume that Stein completely accomodating to her audience. She has no preferences among personae, and only want to maxize her audience's reception of her.

$\nu_{\mathbf{S}}(\mathbf{p})$

Personae	Values
{PRO-VAXX, PRO-CORPORATE}	0
{PRO-VAXX, ANTI-CORPORATE}	0
{ANTI-VAXX, PRO-CORPORATE}	0
{ANTI-VAXX, ANTI-CORPORATE}	0

This assumption is probably most accurate for political discourses where the speaker wants above all to have the listener approve of their persona.

- That said, note that adding a speaker preference will only cause Stein to either dog-whistle in more risky situations (where the audience is perhaps not balanced correctly) or refrain from dog-whistling when it would otherwise be safe to do so

- This means we can safely ignore it to keep the examples less complicated

Finally, Stein believes that listners might not uniformly take certain messages to go with certain persnonae.

- All anti-vaxxers are savy about the phrase "Big Pharma" and it's place in anti-vaxx discourses, but pro-vaxxers either know about Big Pharma or not.

- All speakers realize that a phrase like "corporate scientists" is pro-vaxx, in virtue of mentioning scientists, but anti-corporate (in virtue of tying those scientsts to corporate interests).

- Note that we assume anti-vaxxers and savy pro-vaxxres have she same probability structure below—this actaully attenuates the utility of a dogwhistle. The less an outgroup is aware ingroup messaging, the more useful it will be to dogwhistle.

Anti-Vaxx and Savvy Pro-Vaxx likelihoods for "Big Pharma"
Note that it's possible that a speaker might use the phrase to signal they are just anti-corporate, these listeners know this is phrasing used by their anti-vaxx/anti-corporate allies. Also note this phrasing is inconsistent with a pro-vaxx and pro-corporate persona, which we assume speakers know based on knowing the social meaning of the phrase.

Personae	$Pr(m|p)$
{PRO-VAXX, PRO-CORPORATE}	0
{PRO-VAXX, ANTI-CORPORATE}	.1
{ANTI-VAXX, PRO-CORPORATE}	.1
{ANTI-VAXX, ANTI-CORPORATE}	.8

Unsavvy Pro-Vaxx likelihoods for "Big Pharma"
Note that speakers not aware of anti-vaxx discourse consider this phrase to be consistent with an anti-vaxx persona, but is taken to be primarily an anti-corporate phrase. That is, these speakers don't see the tight connection between "Big Pharma" and anti-vaxx personae.

Personae	$Pr(m|p)$
{PRO-VAXX, PRO-CORPORATE}	0
{PRO-VAXX, ANTI-CORPORATE}	.7
{ANTI-VAXX, PRO-CORPORATE}	.1
{ANTI-VAXX, ANTI-CORPORATE}	.15

Everyone's likelihoods for "Corporate Scientists"
Note that this phrase all but rules out being anti-vaxx, but leans anti-corporate.

Personae	$Pr(m|p)$
{PRO-VAXX, PRO-CORPORATE}	.6
{PRO-VAXX, ANTI-CORPORATE}	.8
{ANTI-VAXX, PRO-CORPORATE}	.1
{ANTI-VAXX, ANTI-CORPORATE}	.1

We now have utilities of the two messages for differnet kinds of listers:

The Savvy Pro-Vaxxer
Note that the Savvy Pro-Vaxxer has a large negative for Big Pharma, which is the

effect of detecting that the phrase "Big Pharma" signals anti-vaxx personae, which they disapprove of.

Message	Utility
Big Pharma	-84
Corporate Scientists	64

The Unsavvy Pro-Vaxxer

Note that in comparison, the Savvy Pro-Vaxxer has a much higher utility for "Big Pharma". This is the dog-whistle effect because the Unsavvy Pro-Vaxxer misses the dogwhistle—namely that "Big Pharma" highly codes for the anti-vaxx persona (the residual negative relative to the message "Corporate Scientists" is from the fact that it doesn't rule out anti-vaxx personas like other phrasing. That is, it is more cagey though doesn't implicate the speaker as an anti-vaxxer to these listeners).

Message	Utility
Big Pharma	32
Corporate Scientists	42

The Anti-Vaxxer

Note that the Anti-Vaxxer shows the opposite pattern from the Savvy Pro-Vaxxer. This is because they also hear the dogwhistle, but like it's message.

Message	Utility
Big Pharma	73
Corporate Scientists	-81

In comparing these utilities, we already see the Type 1 dogwhistle effect, namely a message's utility can be greatly increased when listeners fail to realize how tightly it's correlated with a persona they disapprove of.

- For us, the effect is due to that the fact that a listener's (dis)approval of a persona affects the utility of a message in proportion to probability they assign that persona given the message.

- If some listeners are unaware that a message tightly signals a persona, their reaction to that persona can be discounted relative to other listeners that are aware (and may have opposing reaction).

While we already have an analysis of what makes a Type 1 dogwhistle a dogwhistle, the model also makes predictions about when it is optimal to deploy such language.

- In particular, it makes predictions about audience structure.

- If we sum message utilities over each listener in a audience, the optimal message will depend on the proportion of different types of listeners (the speaker thinks) are in the audience.

In general, given n kinds of listeners, it will be optimal to use a dogwhistle over a disavowal it the following equality holds—where x_n is the number of listeners of type L^n.

(15) $(x_1 * U_S^{Soc}(\text{DOGWHISTLE}, L^1)), ..., (x_n * U_S^{Soc}(\text{DOGWHISTLE}, L^n)) >$
$(x_1 * U_S^{Soc}(\text{DISAVOWAL}, L^1)), ..., (x_n * U_S^{Soc}(\text{DISAVOWAL}, L^n))$

Let's consider our intuitions about the scenarios above.

1. If Stein thinks she is talking to any number of pro-vaxxers, whether or not that person is savvy about anti-vaxx discourse or not, she is best to issue a disavowal.

2. If Stein thinks she is talking to any number of anti-vaxxers, she should obviously not disavow and instead issue the dogwhistle.[2]

3. If Stein is talking in mixed company, there things are more complicated, but the ratio of anti-vaxxers to pro-vaxxers (of both types) will determine whether it's best to dogwhistle.

   (a) If there are too few anti-vaxxers in the mix, she can afford to alienate them, issue a disavowal, and reap the utility of signalling her pro-vaxx stance to a primarily pro-vaxx audience.

   (b) In this calculating, the Savvy Pro-Vaxxers matter more than the Unsavvy. That is, the lower the ratio of Savvy Pro-Vaxxers to Anti-Vaxxers, the more Pro-Vaxxers we need in total to make it worth her while to issue a disavowal.

Our model captures this dynamic.

- First, note that because the utilities for "Big Pharma" / "Corporate Scientists" are $-84/64$ and $32/42$ for Pro-Vaxxers of both types, it is just always better to avoid the dogwhistle if we have a uniformly pro-vaxx audience.

- Second, note that because the utilities for "Big Pharma" / "Corporate Scientists" are $73/-81$ for anti-vaxxers, it is always best to use the former in a pure anti-vaxx crowd.

- Finally, some calculations using the formula in (15) shows that we capture our third intuition above.

  – If there are twice as many Anti-Vaxxers as Savvy Pro-Vaxxers, then it is optimal to use the dogwhistle as long as there aren't more than 16 times as many Unsavvy Pro-Vaxxers as Savvy Pro-Vaxxers.

---

[2]Actually, she may want to issue a direct appeal, but we have not modelled a third explitly anti-vaxx message, though we could. In previous experimental work (e.g., Albertson 2015), listeners who would approve of a direct appeal don't seem to prefer it over the dogwhistle, though this probably depends on their listener model, that is, who they think might else be listening.

- – If we increase the ratio to 4 to 1, then the break-even point is around 50 times the as many Unsavvy Pro-Vaxxers as Savvy Pro-Vaxxers.
  - – More concretely, based on the numbers above, if Stein speaking to audience of 5200 people, it will be optimal to use the dogwhistle if she thinks 400 are hard core anti-vaxxers, 100 are pro-vaxxers who follow the anti-vaxx literature, and the rest are pro-vaxx, but not savvy about anti-vaxx rhetoric.

We believe this seems pretty reasonable, though it would be interesting to study experimentally speakers' tolerances for deploying dogwhistles, given audience size / structure—presumably it has a kind of Weberian distribution that is not modeled here.

- Most importantly for this preliminary work, though, is that we can:

  - – explain what makes for Type 1 dogwhistles languages
  - – capture that fact that deploying a dogwhistle is only optimal when the audience has the appropriate structure.

6   Extending the account to Type 2 dogwhistles

To analyze Type 2 dogwhistles we import the machinery of standard signaling games. Strategy:

- Use signaling games, assuming signals with two possible meanings, one an enriched version of the other

- Let recovery of the enriched version be tied to recognition of the relevant persona by interpreting messages as pairs of truth-conditional meanings and social meanings: $\langle m, [m] \rangle$ and imposing payoff conditions.

For the domain of non-social-meaning communication, we need some additional game components.

- W = a set of states (worlds). Speaker strategies σ are now functions from pairs of states and personae to messages, and listener strategies ρ are functions from messages to such pairs.

- A utility function for information retrieval: Let $\rho(\sigma(p, t)) = (p', t')$. Then

(16) $U_S(m, L) = U_S^{Soc}(m, L) + EU(L, Pr)$, where $EU(L, Pr) = \sum_{t \in T} Pr(t) \times U(t, L)$, where $U(t, L) > 0$ if $t = t'$ and else $= 0$ (cf. van Rooij 2008).

- i.e., the social meaning is always recovered, but if the listener fails to recover the proper truth-conditional meaning, no value is extracted from this aspect of the communication.

- A more elaborated version of this function can be given by weighting the two components of the utilities with values δ, γ, giving

(17) $U_S(m, L) = \delta U_S^{Soc}(m, L) + \gamma EU(L, Pr)$.

- Here δ indexes the value placed on the social meaning and γ the value of the truth-conditional meaning.

- Setting $\delta = 0$ gives an Aspberger's style of communication, where social meaning is disregarded; at the other extreme, setting $\gamma = 0$ gives Donald Trump ('post-truth').

In general, the above seems correct; indeed, it seems correct for Type 1 dogwhistles, where the communicated social meanings and truth-conditional meanings are (at least conventionally) independent. But more needs to be said for Type 2 meanings.

- The reason is that, in these cases, proper recovery of intended (enriched) TC meaning is (co)dependent on identifying the relevant persona.

- We are inclined to view this as a kind of pragmatic encroachment somewhat parallel to the cases discussed by e.g. Recanati 2003.

- However, standard cases are entirely contextually conditioned, while these seem to be the result of a conventional association: once the persona is identified, the additional meaning becomes apparent to the interpreter.

(18)   You're not going to die from that cut. (mom to child on the playground)

This means that Type 1 dogwhistles (etc) are actually a special case. In general, there seem to be two steps in this kind of interpretation. The listener first recovers the speaker's persona on the basis of the utterance, and then uses the result to determine 'what is said'.

- In the present setting, this amounts to conditionalizing prior probabilities on the social meaning and using the posterior probabilities to recover the TC meaning.

This can be modeled by altering the expected utility computation for the TC part of (16) to reference posterior probabilities, as represented by Pr' in (19):

(19) $U_S(m, L) = U_S^{Soc}(m, L) + EU(L, Pr')$, where $EU(L, Pr') = \sum_{t \in T} Pr'(t) \times U(t, L)$, where $U(t, L) > 0$ if $t = t'$ and else $= 0$.

Example.
Consider the utterance (5), with its Type 2 dogwhistle.

- This utterance contains the phrase 'inner cities' which, on its dogwhistled interpretation, means 'African American neighborhoods'.

- Without recognizing Paul Ryan's persona, this interpretation seems to be very difficult to get; but, once the persona is recognized, it is very easy, given knowledge of the relevant signal.

- We analyze this process of interpretation as follows [details redacted]:

  - First, the DW-sensitive hearer recognizes the persona employed by Ryan, which is signaled directly by the use of 'inner cities.'
  - This results in conditionalization on this persona, which in turn drastically raises the probability of the meaning 'African American neighborhoods' to a point at which this meaning is optimally selected.

In general, it seems that knowledge about social personae can play a role in recovering intended meanings. We suggest that dogwhistles are an instance in which they are in fact crucial. It seems likely there are other such cases as well; likely domains might be pejoratives and honorification, but we leave exploration for future work.

7 Conclusion

This paper has:

- Argued against a CI account of dogwhistles on which they introduce mixed content

- Distinguished two types of dogwhistle, both of which convey social personae but only one of which has at-issue content which is influenced by the persona recovered

- Modeled the two types using an extension and variant of Burnett's social meaning games

What is the best characterization of dogwhistles within existing domains of not-at-issue meaning?

- As we have argued, CIs are an improper characterization, for the meaning is not fully conventional.

- Rather, on our analysis, all the action in Type 1 dogwhistles is in the domain of social meaning, which in turn is inferred using information about speech styles and social character, while Type 2 dogwhistles further build on the result of these inferences to alter or enrich at-issue content.

- They share with conversational implicatures the property of being cancellable (deniable), but differ from (standard views of) them in not following from (anything but an extremely nonstandard construal of) the Gricean Maxims.

- Dogwhistles seem to occupy a genuinely new niche in the characterization of not-at-issue meaning.

This area is rich with connections to other areas of semantics and pragmatics, to other aspects of social meaning and sociolinguistics, and to other kinds of political speech. Some immediate next steps for this project include:

- Further consideration of different kinds of mixed audiences: (i) influence of degree of sympathy/antipathy, (ii) relative size of sympathetic group vs unsympathetic savvy vs unsavvy interpreters, for a more abstract characterization, together with experimental confirmation

- Introduction of a repeated game model with concomitant potential for modeling punishment behavior and possible influence on use of dogwhistles (because of new risk in further interactions)

- In repeated game setting, consideration of post-DW communication between audience members: savvy listeners can make unsavvy ones aware of the dogwhistle, influencing subsequent interactions. However, for this we also need a better understanding of what is gained (or potentially lost) by further signalling of personae; currently our use of ln predicts a substantial loss of value after initial learning, which needs to be looked at further

- Extending the model to other kinds of enrichment phenomena and cases in which social personae interact with interpretations of TC content
